Abstract

This paper proposes a flexible multi-standard digital front-end (DFE) hardware architecture designed for three main low-power wide-area (LPWA) technologies: LoRa, Sigfox, and narrowband-Internet of things (NB-IoT). We demonstrate the feasibility of an unified DFE architecture that fits the requirements of these LPWA technologies. The proposed DFE architecture has been implemented on a Spartan-6 field programmable gate array (FPGA) within a base station receiver, and tested using a universal software radio peripheral (USRP) based platform. We show that the expected performance can be achieved with low hardware complexity, in terms of memory and logic requirements.

1 Introduction

The development of the Internet of things (IoT) market has led to a great diversity of wireless connectivity solutions. This paper addresses the low-power wide-area (LPWA) solutions, targeting IoT networks with coverage in the kilometer order, using low-power end devices having a battery life autonomy of multiple years. Various LPWA technologies and standards have emerged, with different air interfaces : LoRa, Sigfox, NB-IoT, LTE-M, DASH7, Weightless, NB-Fi, RPMA, MY-THINGS, and others [1, 2, 3]. In this context where multiple options are possible, there is a need for technical components that are flexible enough to support different technologies. In this paper, we focus on the main LPWA technologies that have been widely adopted and deployed by operators, as part of large ecosystems [4]: LoRa, Sigfox and NB-IoT

The LoRa technology introduced by Semtech uses a chirp-based patented modulation scheme, while the network can be deployed by any third-party entity based on the LoRaWAN open specifications [5] maintained by the LoRa Alliance[1]. Sigfox technology proposed by Sigfox S.A. also uses the unlicensed spectrum, and is based on the differential binary phase-shift keying (D-BPSK) and Gaussian frequency shift keying (GFSK) modulation schemes. Moreover, the network deployment of this technology is controlled by Sigfox. NB-IoT, initially published in Release 13 of the third generation partnership project (3GPP) organization[2], is based on cellular mobile network, using resources within frequency bands allocated to LTE (inband mode), or dedicated to NB-IoT (standalone mode).

This diversity increases the LPWA network deployment cost in case each technology is independently deployed.

To solve the problems of a heterogeneous network, and to efficiently exploit virtualization techniques, the interoperability between these LPWA technologies should be maximized. On the radio front-end level, this is achieved by providing LPWA gateways that are capable of supporting the largest number of technologies. This type of gateways requires a digital front-end (DFE) implementation that provides the flexibility needed to meet the requirements of these different technologies.

This paper proposes a generic approach to build a flexible multi-standard DFE for LPWA technologies. A focus on the hardware implementation of the DFE is presented. A common architecture for the three considered LPWA solutions is proposed, whilst respecting the constraints imposed by their specifications.

The rest of the paper is organized as follows. In section 2, the flexible DFE architecture is presented based on the requirements of the different LPWA technologies. Section 3 presents the hardware implementation of this flexible DFE. Section 4 concludes this work.

2 Multi-standard DFE design approach

2.1 Overview

A preliminary analysis phase of the three protocols allowed us to design the DFE around three blocks shown in Fig. 1, and described as follows:

- Rate adaptation: the sampled signal at the output of the analog to digital converter (ADC) is sub-sampled from sampling frequency f_0 (ADC frequency) to frequency f_1, with $f_1 \leq f_0$. A very efficient and low-complexity rate adaptation is implemented based on [6, 7].

- Filtering: A low-pass finite impulse response (FIR) filter operating at frequency f_1, allows to reject neighbouring interferers and blocking signals, as well as performing a pre-equalization in the band-pass area. Since the computational cost of the filtering step is directly related to the length of the filter (*i.e.* its number of taps), it is designed as short as possible while respecting the requirements. We used our own FIR filter design tool[3] to generate equiripple filters [8].
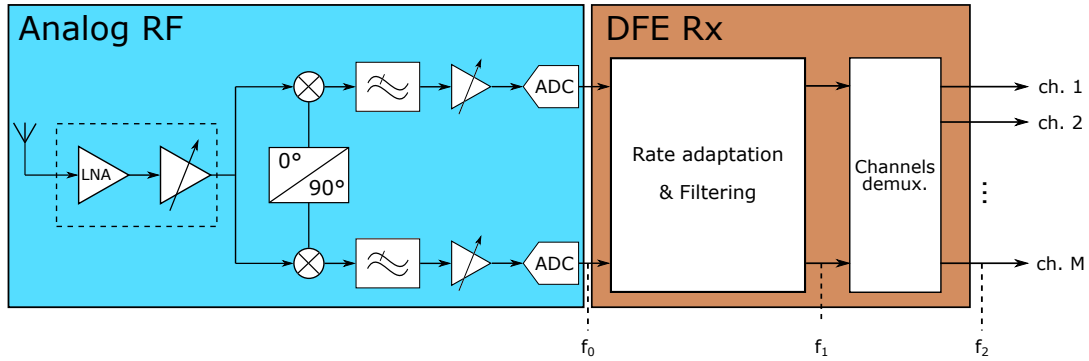

Figure 1. General DFE block diagram, including rate adaptation, filtering, and channels demultiplexing (demux.).

- Channels demultiplexing: the aim of the channels demultiplexing block is to split the whole band into different channels, *e.g.* channels of 125 kHz in LoRa (*i.e.* $f_2 \geq 125$ kHz) or of 180 kHz in NB-IoT (*i.e.* $f_2 \geq 180$ kHz). It must be noted that there is no default channel split defined in Sigfox, so we propose to apply several channel demultiplexing blocks in parallel, using the same input signal with a different frequency shift, so as to use a similar architecture.

These blocks are common to the three technologies, and only require specific parameters to be adapted to each one of these. It then allows for rapid hardware developments of flexible DFEs. Fig. 2 shows an example of frequency response for the rate adaptation, the low-pass filter, and the combination of the latter (referred to as "global"). In this example, the DFE is adapted to the reception of NB-IoT within an LTE band, considering a 5MHz bandwidth. The ADC frequency is set to $f_0 = 60.8$ MHz and the output frequency of the rate adaptation and filtering stage is $f_1 = 7.68$ MHz, corresponding to the sampling frequency of the 5 MHz LTE band. The filter has been designed for a 100dB rejection and a ripple below ± 1 dB. Furthermore, it can be observed that the filter applies an equalization in the pass-band to counterbalance the attenuation due to the rate adaptation block.

2.2 Design constraints

We provide in this section the list of RF performance parameters that impact the DFE design for the targeted air interfaces.

LoRa: LoRa networks are operated in unlicensed bands using a proprietary physical layer (PHY) designed by Semtech. The LoRa PHY main characteristics are listed in Table 1. The European industrial, scientific and medical (ISM) frequency band used for LoRa operation is indicated for the sake of example, but other unlicensed frequency bands are also used according to the geographical area [9].
Based on these characteristics, we have derived the design parameters of our DFE for the LoRa mode of operation as indicated in Table 2. The provided parameters have been
Figure 2. Filter shapes at each step and global filtering. Note that FIR filter compensates the rate adaptation attenuation in pass band.

carefully adjusted to achieve high channel selectivity, assuming the parallel reception of 8 LoRa RF channels with 200kHz channel raster. The output rate of the DFE in this case is 250kSamples/s, which corresponds to a 1MB/s per channel data rate when using 16 bits for each of the I and Q paths.

Sigfox: Sigfox has released their proprietary radio specifications in [10], including the air interface description and the different regional parameters. Table 3 summarizes the radio parameters of the European region. As indicated in this table, the available frequency range for uplink and downlink transmissions spans over 192kHz in both directions. Within this bandwidth, guard bands are reserved at the lower and upper parts of the band to account for the inaccuracies in the reference frequency at the end node (20ppm assumed) and at the network gateway (1.62ppm assumed) sides. The usable frequency band when considering these guard bands is reduced to 154.462kHz, centered at 868.13MHz. For the sake of clarity, let us consider a usable frequency band of 150kHz in the rest of this article.

It is also important to note that the channel bandwidth occupied by the Sigfox signal (100 Hz) is low compared to the channel frequency inaccuracies of the transmitter and receiver ends. For this reason, the Sigfox gateway receiver cannot assume a

Table 1. LoRa PHY characteristics

	Europe
Frequency band	863-870MHz
Duplex mode	half duplex
Channel bandwidth	125kHz
Channel raster	200kHz
Number of channels	3 mandatory, typically 8
Gateway Tx power	20dBm
Modulation	Chirp Spread Spectrum
Spreading Factor	7-12
Coding rate	4/5, 4/6, 4/7, 4/8

Table 2. DFE configuration for LoRa, 8 channels

DFE design parameters	
ADCs output Rate f_0	60.8MHz
Rate adapt. output rate f_1	1.6MHz
Channels demultiplexing output rate f_2	250kSamples/s per channel
number of filter taps	500
Achieved channel selectivity	
carrier offset	rejection
$\pm$85kHz	75dB

Table 3. Sigfox PHY characteristics

	Europe
Frequency band	868.034-868.226MHz uplink 869.429-869.621MHz downlink
Duplex mode	FDD
Channel bandwidth	100Hz uplink & downlink
Modulation	D-BPSK uplink GFSK downlink

Table 4. DFE configuration for Sigfox

DFE design parameters	
ADCs output Rate f_0	60MHz
Rate adapt. output rate f_1	150kHz
Channels demultiplexing output rate f_2	400Samples/s per channel
number of filter taps	24000
Achieved channel selectivity	
carrier offset	rejection
$\pm$200Hz	60dB

3 Hardware Implementation

3.1 Test platform

Our gateway experimentation platform is composed of an off-the-shelf NI USRP B205mini board. This software defined radio (SDR) platform contains the RF transceiver and an Xilinx Spartan-6 FPGA with a $83.3 \times 50.8 \times 8.4$ mm form factor. The DFE function has been implemented in the user programmable FPGA. The receiver also includes, prior to the B205mini RF receiver, an analog front-end board of our own design, that includes a low noise amplifier (LNA) achieving 30 dB gain with 3 dB noise figure (NF) in the 868 MHz ISM band and the LTE band 8. The functional and performance tests are done using IoT (LoRa, Sigfox or NB-IoT) commercial devices.

3.2 FPGA implementation and results

Table 7 summarizes the Rx DFE hardware resources utilization for each of the targeted IoT standards. Four key resources are detailed: registers used to save temporary results and variables, look-up tables (LUTs) that determine the combinatorial behaviour, memories (RAMs) to store parameters such as the filter taps, and digital signal processors (DSPs) that are specialized units for multiplication/addition computation.

This table shows that any of the LoRa, Sigfox or NB-IoT DFEs fits in the small cost-effective B205mini board. The different technologies use similar resources, except for the RAM requirement that is much higher for the Sigfox mode. This is mainly due to the number of channels to be processed in parallel, requiring a large amount of filter taps. The RAM requirement is also higher in case of NB-IoT compared to LoRa. The worst case in NB-IoT inband mode is indeed the 20MHz LTE bandwidth case, where 18 PRBs are dedicated to NB-IoT and need to be extracted in parallel. This impacts the number of filter

fixed channel raster, and must be able to demodulate an uplink modulated signal present at any frequency within the usable bandwidth. In addition, the average RF channel frequency drift observed during a transmission is as high as $\pm$20 Hz/sec due to the reference frequency source drift, and the typical burst duration exceeds 1 seconds. This constraint needs to be addressed when designing the filtering and channel demultiplexing in the DFE

In order to fulfill the above constraints, our proposal is to consider 300Hz wide channels every 200Hz, using two parallel filtering and channels demultiplexing entities. Each parallel entity processes a different version of the received signal shifted by a 200Hz offset. In total, there are 750 channels at the output of the DFE to cover the 150kHz band. The DFE parameters set to implement this Sigfox configuration are provided in Table 4. Note that at the DFE output, the channel bandwidth is 300Hz, so it is required to further process the output of the DFE to demodulate the 100 bauds D-BPSK signal.

NB-IoT: NB-IoT is a cellular LPWA technology introduced in the Release 13 of the 3GPP specifications. In this contribution, we target the NB-IoT inband operation mode, where some LTE resource blocks of 180 kHz bandwidth are allocated to NB-IoT. For instance, four specific resource blocks are defined when NB-IoT is transmitted in the 5MHz LTE band. Our proposal for the NB-IoT operation mode is to use the DFE for the extraction of 180kHz wide physical resource blocks (PRB) within the LTE band. Tables 5 and 6 summarize the NB-IoT constraints and the corresponding configuration, respectively, considering the LTE 5MHz bandwidth, and inband mode.

Table 5. NB-IoT PHY characteristics (inband mode)

Frequency bands	same as LTE
Duplex mode	Half duplex
	FDD
	TDD (release 15)
Channel bandwidth	180kHz
Waveform	SC-FDMA (uplink)
	OFDMA (downlink)
Modulation	$\pi/2$-BPSK, $\pi/2$-QPSK, QPSK
Subcarrier spacing	3.75kHz, 15kHz

Table 6. DFE configuration for NB-IoT inband mode, 5 MHz bandwidth (25 PRBs)

DFE design parameters	
ADCs output Rate f_0	60.8MHz
Rate adapt. output rate f_1	7.68kHz
Channels demultiplexing output rate f_2	240.10^3 Samples/s per channel
number of filter taps	256
Achieved channel selectivity	
carrier offset	rejection
±200Hz	60 0dB

Table 7. FPGA DFE complexity figures

	Registers	LUTs	RAM	DSP
Available	184304	92152	268	180
LoRa	12055	10162	24	68
Sigfox	12282	11019	153	68
NB-IoT	13585	10936	48	74

Figure 3. Sensitivity preliminary measurements for LoRa system

taps that need to be stored within the block. In case of LoRa, the considered number of parallel channels is set to 8, hence the lower memory needs. Moreover, it must be emphasized that a small (cost-effective) FPGA has been used for our test, allowing for the embedding of at most two technologies on the same board. However, the three technologies could be easily embedded on a larger board, allowing for a true multi-standard DFE.

The integration of the DFE within the complete network infrastructure has been initiated, and preliminary measurements have been conducted. Fig. 3 shows some of the sensitivity measurements results obtained for the LoRa case. The curves represent the block error rate as a function of the input signal level, for different spreading factor configurations (SF).
4 Conclusion

In this paper, we present a flexible multi-standard digital DFE for the main LPWA technologies: LoRa, Sigfox and NB-IoT. The solution is based on three hardware subsystems that can be configured and tuned according to the targeted technology: rate adaptation, filtering and channel demultiplexing. In the future, we plan to assess and further improve the full RF receiver performance for the three technologies, and particularly immunity to adjacent signals and blockers. We are also working on the integration of hardware detection blocks dedicated to the above mentioned technologies with encouraging preliminary results.
